Prostate Disease: The Most Comprehensive, Up-to-Date Information Available to Help You Understand Your Condition, Make the Right Treatment Choices, and Cope Effectively

30 Apr 2018. Find out everything you need to know about prostate cancer. Prostate cancer is a disease in which malignant (cancer) cells form in the prostate gland and then spread (metastasize) to other parts of the body. The gland is located just below the bladder, near the base of the urinary tract. The prostate gland surrounds the urethra, the tube that carries urine from the bladder through the penis. The prostate gland is necessary for sex, but it is not necessary for life. The symptoms of prostate cancer can be similar to the symptoms of other conditions such as benign prostatic hyperplasia (BPH), and it may be difficult to tell the difference between the diseases. However, prostate cancer is not caused by BPH. Prostate cancer is one of the most common types of cancer in men in the United States. Men are at greatest risk for developing prostate cancer after the age of 50. The most effective way to detect prostate cancer is by examining the prostate gland during a digital rectal examination (DRE) and by using a blood test to measure the amount of prostate-specific antigen (PSA) in a man's blood. PSA is a substance produced by the prostate gland in small amounts by healthy men. The amount of PSA can increase in the blood of men with prostate cancer. PSA levels can also increase in healthy men who have conditions that cause their prostate gland to grow larger (also called benign prostatic hyperplasia or BPH). PSA levels also can increase in men who have infections or other conditions that cause the prostate gland to become inflamed. Therefore, a high PSA level does not necessarily mean a man has prostate cancer. A low PSA level does not necessarily mean a man does not have prostate cancer. The only way to know for sure whether a man has prostate cancer is by doing a biopsy. A biopsy is when a small sample of tissue is removed from the prostate gland so that the cells can be examined in a laboratory.

The most common symptom of prostate cancer is a feeling of needing to urinate frequently. Other symptoms can include:

- Difficulty starting or stopping the flow of urine
- Straining to start or stop the flow of urine
- A weak or interrupted stream of urine
- Feeling a strong need to urinate even though you have recently urinated
- Waking up two or more times each night to urinate
- A feeling of there not being enough urine
- Blood in the urine (hematuria)
- Incontinence (problems with the bladder that lead to leakage of urine)

The most common risk factors for developing prostate cancer are:

- Age: The risk of developing prostate cancer increases with age. Most prostate cancers are found in men older than 50.
- Family history: If you have a brother, father, or male relative who has been diagnosed with prostate cancer, you may be at higher risk for developing the disease.
- African American ethnicity: African American men are more likely to develop prostate cancer than men of other races. African American men also tend to develop prostate cancer at younger ages than men of other races.
- Lifestyle factors: Smoking and obesity are risk factors for prostate cancer.

Prostate cancer can be divided into three stages:

- Localized prostate cancer: The cancer is in the prostate gland and nearby tissues. It has not spread to different parts of the body.
- Regional prostate cancer: The cancer has spread beyond the prostate gland to nearby lymph nodes.
- Metastatic prostate cancer: The cancer has spread to other parts of the body, such as the bones, lungs, liver, brain, or skin.

The most common treatments for prostate cancer are:

- Surgery: In many cases, surgery is the treatment of choice for men with localized prostate cancer. It is also sometimes used for men with regional prostate cancer. Surgery can be done by cutting out the prostate gland (radical prostatectomy) or by using an electrical current to destroy the prostate gland (prostate cryosurgery).
- Radiation: Radiation therapy is often used to treat prostate cancer that has spread to nearby lymph nodes or to other parts of the body. It can be used as the main treatment for prostate cancer that has spread to the lymph nodes. It can also be used as part of a treatment plan after surgery. Radiation can be given with or without the use of hormones (hormone therapy).
- Hormone therapy: Hormone therapy is often used to treat prostate cancer that has spread to other parts of the body. It can be given alone or with other treatments. Hormone therapy can stop the blood flow to the prostate gland or can reduce the levels of certain hormones that stimulate prostate cancer growth.
prostate cancer is in an early stage, is growing slowly, and treating the Radical (open) prostatectomy. Consider all your treatment options. More information on the specific effects of surgery, chemotherapy, and if.
